MARINE POWER AND EQUIPMENT  
TECHNICAL STATUS REPORT

There were three facets to the Marine Power and Equipment study, namely: Bioassay of sediments, Metals analysis, and a dive survey to determine the quantity of sandblasting debris present at the Marine Power facilities.

#### Sampling for Chemical Analysis

The sampling areas selected in figures 1 and 2 were chosen because of their proximity to areas where sandblasting debris was found on a previous survey.

Composite samples were collected at each of the areas with a VanVeen grab sampler. Three grab samples were collected from an area and mixed in a pre-cleaned stainless steel bucket until the sediment was homogenous. This required 5 to 6 minutes of constant stirring. The homogenized sample was then split three ways: A 1-gallon aliquot for bioassays, an 8 ounce container for metals analysis and an 8 ounce container for organotin analysis in the future. The samples remained refrigerated in ice chests and in the custody of EPA personnel until they were delivered to the EPA laboratory in Manchester, Wa.

The analytical results for metals analysis are contained in appendix A.

Bioassay results are contained in appendix B.

#### Diving Operations

The objective of the dive survey was to find the thickness and areal extent of the deposits of sandblasting debris on the bottom of Lake Union and the Duwamish River.

#### Method

A 100-meter line, which was marked in 5-meter increments, was laid on the bottom of the lake for divers to follow. Divers dug holes into the lake bottom with a trowel at the 5 or 10 meter intervals along the line and measured the thickness of sandblasting debris using a folding carpenter's rule. The measurements and other notes were recorded as divers progressed along the line. After each dive the line was moved to a new location and the process repeated. The Lake Union site was the only site surveyed because of a lack of divers available to do the job.

The results are presented in Appendix C and figure 1.
